

Triage Solution Reference

Product Owner's recommended classifications and reasoning. Open this only after you have recorded your own triage decisions in Jira.

REMINDER: THE SEVERITY VS. PRIORITY MATRIX

	Low Priority	High Priority
High Severity	Fix when time permits (for example., crash on a deprecated browser)	Fix immediately (for example, checkout crash for all users)
Low Severity	Add to backlog (for example, minor UI misalignment)	Fix soon (for example, company name typo on the homepage)

Severity answers: *How badly does this break the software?* — set by QA or developers.

Priority answers: *How soon must the business fix it?* — set by the Product Owner, with QA input.

RECOMMENDED CLASSIFICATIONS

Bug	Severity	Priority	Why
MB-201 Homepage typo	Low	High	Cosmetic, but visible to every homepage visitor
MB-202 Checkout crash	Critical	High	Core path broken for all users, no workaround, blocks revenue
MB-203 IE10 admin crash	High	Low	A real crash, but only on an unsupported, deprecated browser
MB-204 Button misalignment	Low	Low	Cosmetic and low-traffic; no functional impact
MB-205 Search filter	Medium	Medium	Real defect with a workaround; mild discovery impact

THE PRODUCT OWNER'S REASONING

MB-201 — Homepage course title typo (Low Severity / High Priority)

Technically trivial: a typo breaks no functionality, so the severity is Low. But it sits in the homepage hero where every visitor sees it, which damages MindBridge's credibility — so the business wants it fixed quickly. This is the classic Low Severity / High Priority case: fix soon.

MB-202 — Checkout "Place Order" crash (Critical Severity / High Priority)

A 500 crash that blocks checkout for all users with no workaround is a complete failure of a core path, so the severity is Critical. It also stops every enrolment and all course revenue, so the business urgency is the highest possible. Fix immediately.

MB-203 — Admin enrollment report crashes on Internet Explorer 10 (High Severity / Low Priority) A browser freeze and crash is technically severe, so the severity is High. But it only reproduces on Internet Explorer 10, a browser MindBridge officially dropped last year, and the report works on every supported browser. The affected audience is negligible, so the business urgency is Low. Defer, or do not fix.

MB-204 — Account settings button misalignment (Low Severity / Low Priority)

A two-to-three-pixel misalignment is cosmetic with no functional impact, so the severity is Low. It sits on a low-traffic settings

page, affects no workflow, and few users will ever notice, so the business urgency is also Low. Add it to the backlog.

MB-205 — Catalog search filter returns inaccurate results (Medium Severity / Medium Priority)

The filter returns wrong results, which is a real functional defect, but there is a reasonable workaround — learners can still scroll the list and enrol — so the severity is Medium rather than High. It mildly hurts course discovery for many users without blocking anything, making the business urgency Medium. Schedule it for a planned release.

Exact matches are not required. A successful triage means you separated technical impact from business urgency and justified each call with a clear business reason. The two trickiest cases are **MB-201** (Low Severity but High Priority) and **MB-203** (High Severity but Low Priority) — if you identified both cross-quadrant cases and can explain why, you have demonstrated the core skill this activity is designed to build.
